Chapter 1

Introduction

My dissertation, as well as my long-term research, centers around the field of *automated fact checking* through the means of Natural Language Processing (NLP) and its modern methods. The work consists of the analysis of the whole fact-checking process, its subdivision, and simplification into tasks that can be efficiently addressed using the current state-of-the-art NLP methods, collection of data appropriate to benchmark such tasks, delivery of example solutions and their validation against similar research in other languages and related tasks.

The main focus of mine and of our research group are the fact-checking-related tasks in the West Slavic languages (Czech, Slovak, and Polish) and secondarily in English. My contribution has so far been the collection and publication of novel datasets for the fact-checking task and its subroutines, models trained for the tasks and their debate, including the ongoing establishment of metrics that would explainably rate the model success and error rates in terms close to the human notion of *facticity* (which proves to be a challenge on its own, requiring another round of novel research [Koto et al., 2020, Wright et al., 2022]).

My doctoral aim is to cover every step on the path from gathering a factual claim – for example, extracting it from a political debate – to predicting its veracity verdict and justifying it rigorously with hard data. With the recent boom in NLP beginning with the advent of transformer networks and later the Large Language Models (LLMs) [Zhao et al., 2023], few-shot learning [Brown et al., 2020] and prompting [Liu et al., 2023a] a significant part of the research is and has to be an appropriate and timely adoption of new ever-evolving state-of-the-art NLP solutions, based on well-designed studies in our specific context.

Overall, my agenda is to follow up on my published research on fact-checking in Czech with methods that reiterate on our results in other languages and evolving our previous methodology based on transformer *pre-training & fine-tuning* paradigm to a computationally feasible design based on LLMs, which are already exhibiting superiority tasks similar to ours [Chen et al., 2023] in English.

My recent focus within the whole grand fact-checking scheme is the step of *claim generation*, which I aim to establish among the other commonly benchmarked NLP tasks within the scientific community, adjacent to that of *abstractive summarization*. To benchmark the task, one would need a set of metrics that properly reflect phenomena such as *model hallucinations* – a common problem of modern-day LLMs [Ji et al., 2023]. As the exact word-level metrics for NLP generative tasks do not correlate well with human judgement [Zhang* et al., 2020] and model-based metrics are hard to explain, my research also focuses on delivery of a set of human-understandable model-based metrics.

This study aims to show the directions I am taking to address these challenges, the reasoning behind them, my research questions, and the current results that motivated

Figure 1.1: A real-world example of fact checking done by <https://politifact.org>

them.

1.1 Motivation

The spread of misinformation in the online space has a growing influence on the Czech public [STEM, 2021]. It has been shown to influence people’s behaviour on the social networks [Lazer et al., 2018] as well as their decisions in elections [Allcott and Gentzkow, 2017], and real-world reasoning, which has shown increasingly harmful during the COVID-19 pandemic [Barua et al., 2020] and the Russo-Ukrainian war [Stănescu, 2022].

The recent advances in artificial intelligence have unintendedly contributed to the spread of misinformation on social media [Buchanan and Benson, 2019], as well as they hold a large potential for the false content generation [Sebastian, 2023].

Recent research has shown promising results [Thorne et al., 2019] in false claim detection for data in English, using a trusted knowledge base of true claims (for research purposes typically fixed to the corpus of Wikipedia articles), mimicking the *fact-checking* efforts in journalism.

Fact-checking (Figure 1.1) is a process of matching every information within a *factual claim* to its *evidence* (or *disproof*) in trusted data sources to infer the claim veracity and verifiability. In exchange, if the trusted *knowledge base* contains a set of “ground truths” sufficient to fully infer the original claim or its negation, the claim is labeled as **supported** or **refuted**, respectively. If no such *evidence set* can be found, the claim is marked as **unverifiable**¹.

1.2 Automated Fact Checking

Despite the existence of end-to-end fact-checking services, such as politifact.org or demagog.cz, the human-powered approach shows weaknesses in its scalability. By design,

¹Hereinafter labeled as NOT ENOUGH INFO, in accordance to related research.

Figure 1.2: Automated fact-checking pipeline, reprinted from [Guo et al., 2022]

the process of finding an exhaustive set of evidence that decides the claim veracity is much slower than that of generating false or misleading claims. Therefore, efforts have been made to move part of the load to a computer program that can run without supervision.

The common research goal is a fact verification tool that would, given a claim, semantically search the provided knowledge base (stored, for example, as a *corpus* of some natural language), propose a set of evidence (e.g., k semantically nearest paragraphs of the corpus) and suggest the final verdict (Figure 1.2) [Guo et al., 2022]. This would reduce the fact-checker’s workload to mere adjustments of the proposed result and correction of mistakes on the computer side.

The goals of the ongoing efforts of FactCheck team at AIC CTU are to explore and adapt the state-of-the-art methods used for fact verification or similar tasks in other languages, curate appropriate datasets for it and propose strong systems for such a task in Czech.

1.3 A word on the Transformers

For the past six years, the state-of-the-art solution for nearly every Natural Language Processing task is based on the concept of *transformer networks* or, simply, *Transformers*. This has been a major breakthrough in the field by [Vaswani et al., 2017], giving birth to the famous models such as Google’s BERT encoder [Devlin et al., 2019] and its descendants, or the OpenAI’s GPT-3 decoder [Brown et al., 2020] and GPT-4 [OpenAI, 2023] that are used in the booming online AI service ChatGPT².

In our proposed methods, we use Transformers in every step of the fact verification pipeline. Therefore, we would like to introduce this concept to our readers to begin with.

Transformer is a neural model for *sequence-to-sequence* tasks, which, similarly, e.g., to the *LSTM-Networks* [Cheng et al., 2016], uses the Encoder–Decoder architecture. Its main point is that of using solely the *self-attention* mechanism to represent its input and output instead of any sequence-aligned recurrence [Vaswani et al., 2017].

In essence, the *self-attention* (also known as the *intra-attention*) transforms every input vector to a weighted sum of the vectors in its neighbourhood, weighted by their *relatedness* to the input. One could illustrate this on the *euphony* in music, where every tone of a song relates to all of the precedent and successive ones, to some more than to others.

The full Transformer architecture is depicted in Figure 1.3.

1.4 Dissertation minimum study outline

- **Chapter 1** introduces the dissertation topic, motivates the research, sets up our challenges for future research
- **Chapter 2** examines the most relevant research in the field and tries to highlight the recent paradigm shift from models trained for a single task to single large models that perform well in everything
- **Chapter 3** explains our current contributions to the field of automated fact-checking and NLP in Czech
- **Chapter 4** describes our plan for the dissertation and justifies the directions we are taking
- Finally, **Chapter 5** concludes the study with a wrapup of its findings

Chapter 2

State of the Art

This chapter will first describe the originally popular models for general NLP, such as BERT and the recent paradigm shift from *pretrain + finetune* transfer learning framework popular since the original [Devlin et al., 2019] paper to the currently booming LLMs, which often outperform the smaller models even without the fine-tuning step [OpenAI, 2023, Touvron et al., 2023a, Vicuna, 2023]. We will then take a look at the performance optimization methods that enable training multi-billion parameter pre-trained models on a set of task-specific data on a single GPU and their potential for our research.

To show how it relates to our main topics, we will introduce currently published approaches for the automated fact-checking task, efforts related to claim generation, and evaluation of NLP model outputs.

2.1 Pretrain + Finetune

For the last decade, the *pretrain-finetune* paradigm has been a cornerstone in Natural Language Processing (NLP). It has significantly shaped the development of modern NLP models. Its use in NLP can be traced back to the advent of neural networks and deep learning in the early 2010s. Initially, researchers pre-trained word embeddings using methods like Word2Vec [Mikolov et al., 2013] and GloVe [Pennington et al., 2014], which captured semantic relationships among words and then tweaked the general-task models for various related tasks.

2.1.1 BERT and derivatives

The *pretrain-finetune* paradigm truly rose to fame with the introduction of transformer-based models, particularly the revolutionary BERT (Bidirectional Encoder Representations from Transformers) in 2018. BERT [Devlin et al., 2019] demonstrated the power of pretraining large-scale language models on massive text corpora using an easy-to-automate general task such as *Masked Language Modeling*, or *Next Sentence Prediction*, followed by fine-tuning on specific downstream tasks using smaller, harder-to-obtain data. This approach achieved state-of-the-art results across various NLP benchmarks. Subsequently, numerous variations of pre-trained models like GPT (Generative Pre-trained Transformer) and RoBERTa emerged, each refining the pretrain-finetune paradigm to improve language understanding, generation, and transfer learning capabilities.

Importantly, BERT's success inspired many publications in training similar transformer models, varying in the definition of the general pre-training task, model size, architecture training corpus

- In Czech language, monolingual models CZERT [Sido et al., 2021], FERNET [Lehečka and Švec, 2021], RobeCzech [Straka et al., 2021], and small-e-czech [Kocián et al., 2021] are available for further finetuning
- In Polish, HerBERT [Mroczkowski et al., 2021] achieved state-of-the-art in multiple tasks in 2021
- In Slovak, SlovakBERT [Pikuliak et al., 2021] was released by KInIT and Gerulata
- A multitude of multilingual models, such as M-BERT or XLM-ROBERTA [Conneau et al., 2019] were pre-trained on data in all three of these languages (and many others), proving that the large transformers can capture a notion of semantics and relations between pieces of text even *without* the convenient constriction of a single language

2.2 Few-shot and Zero-shot learning

The ever-growing (sometimes billions of parameters in size) transformer models have not only demonstrated superior performance on benchmark datasets but have also shown remarkable zero-shot and few-shot learning abilities, where they can perform tasks with minimal or no task-specific training data [Brown et al., 2020].

Few-shot learning refers to the capability of a model to perform a task when provided with only a limited amount of labeled examples. Zero-shot learning takes this concept a step further by enabling models to tackle tasks they have never seen during training. The integration of these learning paradigms into large language models like GPT-3 and subsequent iterations has spread the NLP hype even further. By utilizing a prompt or a few examples, these models can quickly adapt to new tasks, making them highly versatile, adaptable, and usable to the general public.

2.2.1 OpenAI LLMs: GPT-3 and GPT-4

In 2020, the few-shot learning was exhibited on GPT3 – a 175B-parameter autoregressive model trained by [Brown et al., 2020]. The model was trained on the task of generating text based on user’s and its own previous outputs. The training procedure and data¹ is thoroughly described in the publication. However, it is prohibitively costly for most labs to reproduce or even fine-tune at such a scale.

In the fall of 2022, GPT-3 became widely popular thanks to its ChatGPT² fine-tune and demonstration app, which puts the user in the role of *prompter*, texting back and forth with an LLM that predicts the most fitting reply to each conversation.

With the arrival of GPT-4, the ChatGPT was already massively famous, and the new model already shipped with a paid-service business scheme no longer publishing the training data, tasks, or even model size [OpenAI, 2023].

2.3 Open source LLMs

This puts the research community in an awkward position, as the GPT-4 achieves state-of-the-art in numerous NLP benchmarks [OpenAI, 2023, Liu et al., 2023b], but is designed

¹A mixture of crawled websites, books, and Wikipedia.

²<https://chat.openai.com>

not to be used in any way other than as a black box, making the derived research rigorosity and reproducibility disputable.

From the prediction times, OpenAI claims, and general trends in NLP, there are also reasons to believe that GPT-4 is orders of magnitude larger than already wasteful GPT-3. This motivates an uptick in research of other LLMs that would be able to operate on a smaller scale with similar results, using a peer-reviewed architecture, training scheme, and data that is available in open source.

2.3.1 LLaMA-2 and derivatives

A popular foundational LLM to compete with the GPT family has become the LLaMA [Touvron et al., 2023a] from Meta research. LLaMA was trained on about 5TB of publicly available textual data³ mainly in English.

It comes in various sizes between 7B and 65B parameters, achieving a SOTA among open-source solvers in various tasks and an unmatched performance in the field of single-GPU (7B and 13B) model sizes. LLaMA proceeds to be used as a goto base model for a number of successful open-source chatbots such as Alpaca [Taori et al., 2023], Vicuna [Vicuna, 2023], and OpenAssistant [Köpf et al., 2023].

The pre-trained LLaMA weights are, however, published under a restrictive license that prohibits republishing the model weights even after tuning its parameters, which limits its fine-tuners to publishing delta- or xor-weights that can not be properly used without Meta’s permission.

LLaMA-2 [Touvron et al., 2023b] addresses this inconvenience (as well as delivers its own take on the *chatbot* task), yielding an ideal strong base model for experimentation with any NLP task in 7B, 13B, and 70B sizes. The only obstacle left in the way is the computational cost of fine-tuning across so many parameters.

2.3.2 LoRA and other optimization

To be able to fine-tune multi-billion-parameter models such as LLaMA-2 [Touvron et al., 2023b] on a single TPU, successful approaches have been published to dramatically cut down the training expenses. Parameter-efficient fine-tuning (PEFT) [Liu et al., 2022a] proposes approaches to only fine-tune *a few* weights as opposed to the whole neural network, reducing the number of trainable parameters by orders of magnitude. Low-Rank Adaptation of Large Language Models (LoRA) [Hu et al., 2021] does so by freezing the pre-trained model weights and injecting trainable rank decomposition matrices into each layer of Transformer architecture.

Quantization, which cuts the costs of working with 32- or 16-bit float parameters and opting for data types of bitsize as small as 4, also proves to be a powerful tool for LLM finetuning performance optimization [Dettmers et al., 2023]. Quantized QLoRA takes LLaMA and finetunes it into a Guanaco model family, which outperforms all previous openly released LLMs on Vicuna benchmark [Dettmers et al., 2023] and achieves 99.3% of the ChatGPT’s performance on it while only requiring 24 hours on a single GPU.

As per an alleged leaked Google memo [Patel and Ahmad, 2023], this could put the future state of the art in NLP disciplines back into the hands of open source and public research, not giving any of the big tech companies a “moat” advantage.

³To be specific, LLaMA was trained using an autoregressive language modeling task on a mixture of English CommonCrawl Corpus, C4 [Raffel et al., 2020], Github, Wikipedia, Gutenberg Project, Books3 corpus, ArXiv and Stack Exchange

Either way, it goes to show that the open-source LLMs have a promising future in NLP and will be indissmissible as an approach for the NLP task of *Automated fact checking*.

2.4 Fact checking approaches

Back in the late 2010s, the misinformation and its spread in the era of the internet and social media became a discussed topic in the Western world, with multiple institutions such as the European Council marking it a severe threat to democracy and national safety [Wardle and Derakhshan, 2017]. The public attention and maturation of appropriate technologies motivated numerous efforts in business and academia to tackle the challenge. Among other events, a Fake News Challenge occurred in 2017 [Pomerlau and Rao, 2017] exploring the uses of technologies in the field and applying, for example, the LSTMs to detect stances among textual data [Hanselowski et al., 2018].

2.4.1 FEVER and followups

Soon, standard tasks began to be formulated and data collected. The FEVER (Fact Extraction and VERification) [Thorne et al., 2018a] dataset and shared task became prominent in natural language processing research. Relatively early on, it formalized the task as a two-step problem:

1. Retrieving information within a structured corpus to fact-check a given claim (this resembles a standard NLP problem called *information retrieval* – IR)
2. Classifying the inference relation between retrieved information and claim as one of:
 - a. **supports** – information semantically implies the claim
 - b. **refutes** – information semantically implies the negation of the claim
 - c. **not enough info** otherwise

This classification task became known as *natural language inference* and mostly replaced the previous binary classification NLP task of *recognizing textual entailment* (RTE)

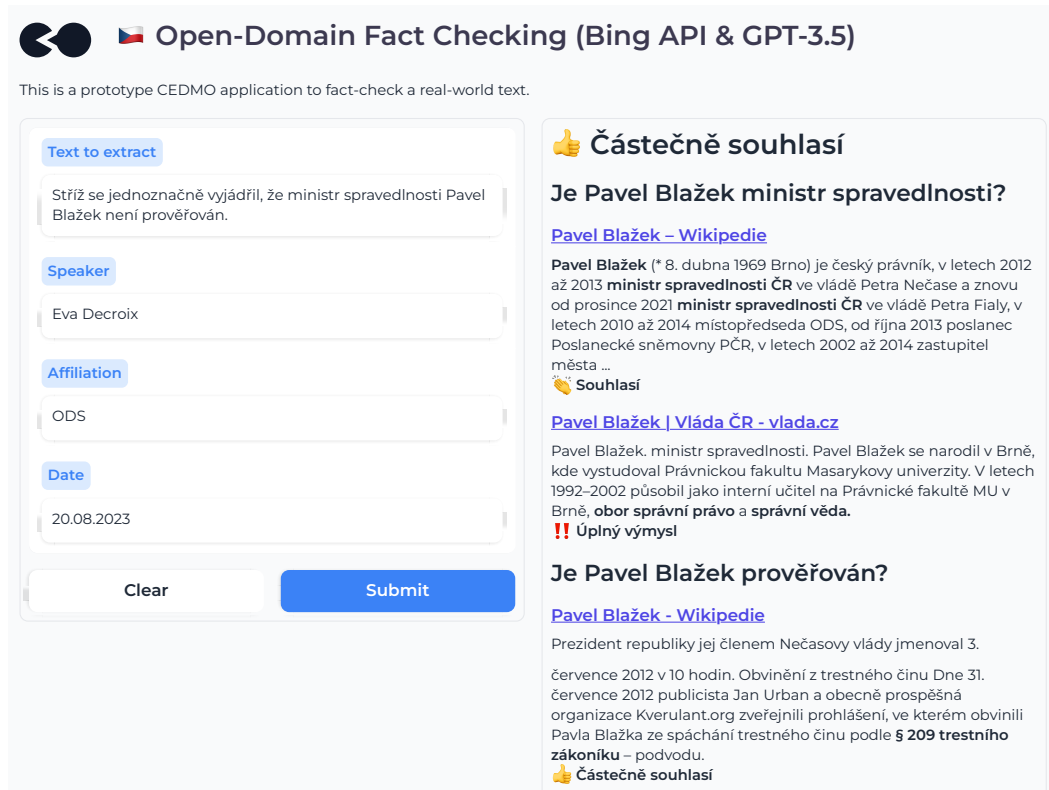

The FEVER dataset was a collection of 185K human-annotated claims, their veracity labels, and sets of evidence from a structured corpus that sufficed to justify the labels. The corpus of choice was a 2017 English Wikipedia structured into articles due to its reasonable size, informational richness, and open license.⁴

FEVER yields an interesting benchmark with statistically quantifiable model success, motivated multiple well-performing public solutions [Thorne et al., 2018b, Thorne et al., 2019], gives insights into the complexities of automated fact-checking task, and strong baselines for research in the field. The data was later enriched by contrastive evidence in VitaminC [Schuster et al., 2021] and by reasoning over tabular data in FEVEROUS [Aly et al., 2021].

To date, it keeps being a reference point in automated fact-checking research despite its limitations, such as its requirement for a fixed knowledge base and “atomicity”⁵ of claims.

⁴Is Wikipedia a trustworthy informational canon, though? No, it is not supposed to – FEVER states that it is crucial to always maintain that the fact-checking classifiers only classify *with respect to* data, and their reliability goes only as far as that of the underlying knowledge corpus. Therefore, *supports* does not directly translate to *true*, nor *refutes* to *false*

⁵See section 4.1.2.3

Open-Domain Fact Checking (Bing API & GPT-3.5)

Figure 2.1: Proof-of-concept Czech fact-checking based on live-internet search (Bing API) and LLM prompting, based on the proposals of [Chen et al., 2023] in Czech, using a real-world claim that was fact-checked by demagog.cz in June 2023

2.4.2 Open-domain fact-checking

Due to these limitations, some researchers consider the scheme from FEVER an oversimplification – the real politics’ claims to be fact-checked by journalists often consist of long syntactical structures, combine information together in a non-trivial manner and often require the most up-to-date evidence.

“Complex Claim Verification with Evidence Retrieved in the Wild” [Chen et al., 2023] proposes a different scheme that overcomes these shortcomings:

1. Arbitrarily complex claim is decomposed into a set of yes/no questions
2. An open-domain search (Bing is proposed in the paper) fetches several evidence documents for each question
3. A claim-focused summary is extracted from each document
4. A veracity classifier goes through each pair of evidence and question, ranging from “faithful” to “completely wrong”
5. The scores are combined (all need to be “faithful” for a faithful claim. Otherwise, the severity of inaccuracies can be approximated using some averaging).

GPT-3 is used in steps 1, 3, and 4 of the scheme in the prototype delivered in [Chen et al., 2023] in a few- and zero-shot fashion, with few-shot unsurprisingly coming out a little better. The scheme is transducible to Czech, and Figure 2.1 shows my early experiments

with my interactive reproduction of it, predictors based on Bing and GPT-3.5 (a polished version of GPT-3).

While the shift from an established FEVER framework to complex real-world claims and evidence retrieval “in the wild” feels exciting and practical, an obvious pitfall arises – anyone can publish anything on the internet, having it appear in Bing search and other crawlers alike. I argue that this might lead into a sort of a circular dependency of needing to reliably fact-check the evidence we have retrieved from the web in order to be able to build a reliable fact-checker in the first place.

Anyhow, the open-domain fact-checking idea opens a whole new range of approaches and shows the power of LLMs in fact-checking at its every step.

2.5 Claim generation

Another step of the fact-checking pipeline, covered by very few research publications, is the generation of the claim to be checked in the first place [Guo et al., 2022].

The current state of things is that journalists who fact-check statements within, say, a Facebook status, need to read through the whole document multiple times, formulate its factual claims from the stances and facts expressed in the text themselves, and then fact-check each separately.

What has been examined so far were, for example:

- Using Question Generation (QG) solver and converting the questions into declarative sentences to emulate more claims and more data for fact checking [Pan et al., 2021]
- Numerous CLEF CheckThat! challenges explored the task of estimating *checkworthiness* of different parts of a long text, such as lines in a political debate [Elsayed et al., 2021, Nakov et al., 2021]
- The task of extreme summarization (XSum) consists of summarizing a long body of text into a single sentence, focusing on its most relevant aspects and facts. Large datasets XSum [Narayan et al., 2018] in English and XL-Sum [Hasan et al., 2021] in 44 languages both present expertly annotated data from BBC News for it, as their article standard features a single-sentence summary at the beginning of each text.

2.5.1 NLP summarization benchmarking

An important caveat to note with the NLP tasks reducing longer text to shorter text – such as summarization or claim extraction – is that the standard automatic metrics such as ROUGE [Lin, 2004] and METEOR [Banerjee and Lavie, 2005] only focus on the *content selection* aspect of tasks, based on a word-by-word overlap and were designed to use on multiple gold summaries per input, which are not often provided with modern large-scale datasets. [NLP-Progress, 2023, Zhang* et al., 2020, Zha et al., 2023]

These serious limitations make it questionable for anyone to claim state-of-the-art on these tasks and motivate research for new metrics to cover all the important aspects of claim generation and do so in correlation with expert human judgment.

This will be the topic of section 4.2, which also introduces the state-of-the-art research we are working with to arrive to a valid set of benchmarks.

Chapter 3

Current Contribution

We have collected novel data for the fact-checking task in our application context, emulated and scraped unavailable datasets, making them public or readying them for doing so, we have established numerous state-of-the-art models and we are currently working on establishing the topic of claim generation as a summarization-related NLP task.

3.1 Datasets

Having the automated fact-checking scheme established in chapter 2, every machine-learning solution must start with the choice or collection of appropriate training data. Due to the novelty of the task in Czech and other West Slavic languages, I explored a multitude of ways to acquire such data, many of them resulting in a publicly available dataset in our Huggingface repository ¹, beginning to be reused by others.

3.1.1 CsFEVER

An early “temporary benchmark” for our endeavors in adapting the FEVER [Thorne et al., 2018a] task for the Czech context was the CsFEVER [Ullrich et al., 2023] dataset.

In [Ullrich, 2021], I have proposed a simple FEVER data transduction scheme that can be simplified as follows:

1. Each FEVER claim is translated using a Machine Translator
2. Evidence from English Wikipedia is not translated using MT, but mapped onto its Czech-Wikipedia counterpart using the publicly available Wikidata²
3. Data with any loss in evidence due to step 2. is discarded

This design was relatively cheap to compute (as translating the whole 2017 Wikipedia corpus would have been a long and wasteful computation), delivering an open-license dataset of 127K claims, their labels, and evidence justifications. My hope was, as both the 2017 EnWiki and our 2020 CsWiki corpus only featured the first paragraph (abstract) of each article, a document-level alignment could be assumed – both the Czech and English text always summarize the basic facts about the same entity.

This showed to be only partly true as a later human annotation on a 1% sample of CsFEVER data showed that about a third of data exhibits some levels of noise, mostly introduced during dataset translation [Ullrich et al., 2023].

¹<https://huggingface.co/ctu-aic>

²Used, for example, for showing the “see this article in other languages” suggestions in Wikipedia sidebar

While noisy, the CsFEVER data still got its use in the training of the information retrieval schemes of [Rýpar, 2021, Gažo, 2021, Ullrich et al., 2023] used to this day and is openly available³ under a CC license.

My research on it also motivated the creation of an inference-only version of the dataset, which does not support the Information Retrieval task and, therefore, does not require the mapping of evidence into a live version of Wikipedia. Therefore, only the EnWiki *excerpts* needed to build evidence can be translated, bringing down the computational difficulty and enabling me to deliver a dataset without the transduction noise called CsFEVER-NLI⁴.

Another round of research CsFEVER motivated, and I supervised, was the successful thesis of [Mlynář, 2023], modernizing the data and machine-translation methods into the 2023 state of the art. [Mlynář, 2023] further experimented with methods of automated noise detection and removal, which has not shown to be an efficient way to tackle the issue of high noise in CsFEVER.

Anyhow, it delivers a partly cleaned version of it⁵ and motivates future research to generate such data differently, using a claim generation scheme like that from [Pan et al., 2021].

3.1.2 FCheck Annotations Platform

The imperfections in translated CsFEVER data, as well as the ongoing collaboration with ČTK and the Faculty of Social Sciences, brought me to also look for ways how to hand-annotate a whole new natively Czech dataset, which would both lack the noise introduced in translation and also take the task of automated fact-checking to the next level, replacing a rigid, simple Wikipedic data with a more “real world” news report corpus of ČTK.

Figure 3.1 shows an open-source platform FCheck⁶ I developed to collaborate with 316 FSV CUNI students of on a collection of novel dataset in Czech using ČTK data as a ground truth corpus.

The figure displays the FCheck platform interface, which is designed for creating, varying, and annotating claims for fact-checking. It consists of four main panels:

- Tvorba tvrzení (Ú1a):** This panel shows the process of creating a claim. It includes a 'Zlatá pravidla extrakce tvrzení' (Golden rules for claim extraction) section with guidelines on how to extract claims from text. Below this, there's a 'Zdrojový citace' (Source citation) section where a claim is entered, followed by a 'Zdrojový odstavec' (Source paragraph) section where the context is provided. The 'Znalostní rámec' (Knowledge frame) section allows for adding related information. Finally, the 'Pravidla tvrzení' (Claim rules) section defines the conditions for the claim.
- Obměny tvrzení (Ú1b):** This panel shows the process of creating variations of a claim. It includes a 'Původní tvrzení' (Original claim) section, followed by a 'Parafraze' (Paraphrase) section where the claim is reworded. Below this, there's a 'Nahrazení podstatnou entitou nebo vztahem' (Replacement of a substantive entity or relationship) section where specific parts of the claim are replaced. The 'Změna kontextu' (Change of context) section allows for changing the background information. Finally, the 'Negace' (Negation) section allows for negating the claim.
- Anotace správnosti vlastního tvrzení (Ú2a):** This panel shows the process of annotating the accuracy of a claim. It includes a 'Tvrzení' (Claim) section where a claim is entered, followed by a 'Podmínka anotace' (Annotation condition) section where the conditions for annotation are defined. The 'Důkazy potvrzující/vyvracející tvrzení' (Evidence supporting/refuting claim) section allows for adding evidence that either supports or refutes the claim.
- Důkazy potvrzující/vyvracející tvrzení:** This panel shows the process of adding evidence to a claim. It includes a 'Zdrojový citace' (Source citation) section where a claim is entered, followed by a 'Zdrojový odstavec' (Source paragraph) section where the context is provided. The 'Znalostní rámec' (Knowledge frame) section allows for adding related information. Finally, the 'Pravidla tvrzení' (Claim rules) section defines the conditions for the claim.

Figure 3.1: FCheck – a platform for fact-checking data collection developed for TAČR project; collects data for claim generation, information retrieval, and natural language inference tasks

⁶[https://fcheck.fel.cvut.cz \(testuser\)](https://fcheck.fel.cvut.cz (testuser)), source at: github.com/aic-factcheck/fcheck-annotations-platform

We have established a 4-step annotation procedure inspired by the time-proven methodology of [Thorne et al., 2018a] where check-worthy paragraphs are first hand-picked among samples from the whole archive of ČTK’s 3.3 M news reports published between 1 January 2000 and 6 March 2019. Then, the annotator is sampled such a paragraph and asked to *extract claims* from it, i.e., formulate single-sentence summaries of some facts that appear in the paragraph. This claim is always *supported* by the data, so the next phase is to perturb the claim by the annotator’s world knowledge and form the claim *mutations* – substitutions of entities, generalizations, specifications, paraphrases or negations of the original claim. The mutated claim is then fact-checked by (typically) another annotator, using the ČTK data narrowed down to a reasonable number of relevant articles (in an IR sense) as *supportable*, *refutable* or *not enough info*, providing a set of evidence as a verdict justification.

The whole application is running on multiple levels – a yii-framework-powered PHP app is running the annotation interface, while a flask server in Python is running our models based on TF-IDF [Chen et al., 2017] and mBERT (section 2.1.1) for information retrieval trained among other data on the CsFEVER dataset (section 3.1.1). The models are solving the Information Retrieval task on-demand (with cache) on the proprietary ČTK corpus whenever the annotation app needs it to provide context to the fact-checker.

The scheme and its implementations are exhaustively described in [Ullrich, 2021], chapter 4, and in [Ullrich et al., 2023], also chapter 4. Multiple “cross-annotations” were collected for each claim to measure agreement and give insights into task complexity.

3.1.3 CTKFACTS

After completing the first year of annotation experiments, we have extracted a total of 3,116 multi-annotated claims. 47% were **SUPPORTED** by the majority of their annotations, **REFUTES** and **NEI** labels were approximately even, the full distribution of labels is listed in Table 3.1.

	CTKFACTS uncleaned, balanced			CTKFACTS (launch) cleaned, stratified		
	SUPPORTS	REFUTES	NEI	SUPPORTS	REFUTES	NEI
train	1,164	549	503	1,104	556	723
dev	100	100	100	142	85	105
test	200	200	200	176	79	127

Table 3.1: Label distribution in CTKFACTS splits before and after cleaning. Reprinted from [Ullrich et al., 2023]

Of all the annotated claims, 1,776, that is 57%, had at least two independent labels assigned by different annotators. I used this multiplicity to assess the quality of our data and the ambiguity of the task, as well as to propose annotation cleaning methods used to arrive at our final cleaned CTKFACTS dataset.

Inter-Annotator Agreement

Due to our cross-annotation design, I had a generously sized sample of independently annotated labels in our hands. As the total number of annotators was greater than 2, and as missing observations were allowed, I have used the Krippendorff’s alpha measure [Krippendorff, 1970] which is the standard for this case [Hayes and Krippendorff, 2007]. For the comparison with [Thorne et al., 2018a] and [Nørregaard and Derczynski, 2021], I also list a 4-way Fleiss’ κ -agreement [Fleiss, 1971] calculated on a sample of 7.5% claims.

I have calculated the resulting Krippendorff’s alpha agreement to be 56.42% and Fleiss’ κ to be 63% and interpreted this as an adequate result that testifies to the complexity of the task of news-based fact verification within a fixed knowledge scope. It also encourages a round of annotation-cleaning experiments that would exploit the number of cross-annotated claims to remove common types of noise.

CTKFACTS publication

CTKFACTS dataset was then subject to a thorough human-in-the-loop data cleaning until a 100% agreement among the data was reached, in order to remove data that contains obvious noise and reveal phenomena that lead to erroneous annotations. The full process, as well as its results, are described in [Ullrich et al., 2023].

Ultimately, a dataset of 3.1K thoroughly cleaned data points in the form of a factual claim, its veracity label and justifications consisting of ČTK paragraphs was published in a version for Information Retrieval⁷ for those who have access to the ČTK knowledge base to retrieve from, as well as in a special version for the task of Natural Language Inference⁸ containing all the required ČTK excerpts we have negotiated to publish under open license for everyone to use.

The datasets have become our standard benchmark within the AIC NLP group [Semin, 2023, Mlynář, 2023] and are starting to be referred and used in others’ research in the field [Štefánik et al., 2023].

3.1.4 Other NLP datasets in West Slavic languages

Over time, we have accumulated numerous sets of data in Czech and other Slavic languages that have previously been poorly covered or not available at all, some of which are to be referred in our future publications. For the convenience of others, most of them are already listed in our public repositories. Let us mention some significant examples:

1. We have machine-translated the most popular NLI training and benchmark datasets such as Stanford NLI [Bowman et al., 2015], Adversarial NLI [Nie et al., 2019b] and MultiNLI [Williams et al., 2018] picking a machine translator empirically for each dataset between DeepL [DeepL, 2021], Google Translate [Google, 2021] and CUB-BITT [Popel et al., 2020].

The resulting datasets are maintained at our public repositories:

- a. https://huggingface.co/datasets/ctu-aic/snli_cs
 - b. https://huggingface.co/datasets/ctu-aic/anli_cs
 - c. https://huggingface.co/datasets/ctu-aic/multinli_cs
2. For the task of claim generation we are establishing and performing in Czech, we have adapted the existing related datasets and are working with:
 - a. CTKSum – <https://huggingface.co/datasets/ctu-aic/ctksum> based on source articles and extracted claims within the original CTKFACTS set
 - b. FEVERSum (based on FEVER Wikipedia abstract and extracted claims) – <https://huggingface.co/datasets/ctu-aic/fever-sum>

⁷<https://huggingface.co/datasets/ctu-aic/ctkfacts>

⁸https://huggingface.co/datasets/ctu-aic/ctkfacts_nli

- c. Its DeepL translation CsFEVERSum – <https://huggingface.co/datasets/ctu-aic/csfever-sum>
- d. Our reproduction of a crawled Slovak summarization dataset described by [Šuppa and Adamec, 2020] SMESum based on articles from <https://sme.sk> – <https://huggingface.co/datasets/ctu-aic/smesum>

Up until now, some of the data was restricted to private repositories, but with this study, I am publishing most of them, as I have now found the licensing to be rather relaxed. If some of the repositories the reader might be interested in would not be reachable, please request access to the <https://huggingface.co/datasets/ctu-aic> organization to be able to see into the private part of our dataset library.

3.2 Models

The most significant pre-trained models I have made public address two tasks – the Natural Language Inference and Claim Generation viewed as a form of Abstractive Summarization task.

3.2.1 Natural Language Inference

My previous work [Ullrich, 2021, Ullrich et al., 2023] also focused on establishing a strong starting state of the art on our own datasets in the tasks of NLI. In my publications, I have tried and compared a multitude of neural networks for the tasks, ultimately arriving at the following:

- **XLM-RoBERTA-Large@XNLI@CsFEVER-NLI**, a model with 561M parameters trained on 100-language CommonCrawl corpus finetuned on multilingual XNLI [Conneau et al., 2018] inference dataset and then finetuned *again* on the CsFEVER-NLI task yields an unmatched 73.7% F1 macro score on the denoised CsFEVER-NLI inference task: https://huggingface.co/ctu-aic/xlm-roberta-large-xnli-csfever_nli
- **XLM-RoBERTA-Large@SQuAD2**, a model version finetuned on a Question answering SQuAD2 [Rajpurkar et al., 2016] task has shown remarkable practicality in my NLI applications and after task-specific finetuning, it was able to tackle:
 1. CTKFACTS⁹NLI task with 76.9% macro-F1
 2. CsFEVER¹⁰ (noisy) task with 83.2% macro-F1
 3. The original English FEVER NLI task¹¹ [Thorne et al., 2018a, Nie et al., 2019a], achieving 75.9% macro-F1 and a significant superiority over previous shared task winner [Nie et al., 2019a] (which had 69.5 macro-F1 with NSMNs)

3.2.2 Claim generation

In my current research, I am finding appropriate configurations and data to train models for claim generation – generating a factual claim (or more) into a single sentence containing a fluent, atomic, decontextualized, and faithful claim. In section 4.1, I propose the claim

⁹https://huggingface.co/ctu-aic/xlm-roberta-large-squad2-ctkfacts_nli

¹⁰https://huggingface.co/ctu-aic/xlm-roberta-large-squad2-csfever_nearestp

¹¹https://huggingface.co/ctu-aic/xlm-roberta-large-squad2-enfever_nli

generation as an abstractive summarization setting, and therefore, the models already have their practical use in the general task of summing up longer texts into shorter ones.

As has been shown in section 2.5.1, the NLP summarization task does not have a reliable standard benchmark that would capture all its required output qualities. Therefore, it remains questionable to claim the state of the art on any summarization task, and I proceed to present models that excel in our empirical tests and demonstrations for project stakeholders:

1. **mBART** [Liu et al., 2020] multilingual Transformer model has been finetuned by our team’s [Krotil, 2022] on SumeCzech and proprietary CNC News summarization dataset on the “full text to headline” task, obtaining encouraging scores across numerous summarization metrics in Czech.

I have taken this model a step further for the claim generation task, finetuning it on the CsFEVERSum and CTKFACTSSum datasets, yielding a working model for the task.¹²

Another experiments are being carried out with the same model finetuned on Slovak¹³ and Polish¹⁴ data.

2. **LLaMA-2** shows promissing result when it comes to claim generation. I have finetuned¹⁵ it using the QLoRA (section 2.3.2) approach, XL-Sum [Hasan et al., 2021] dataset and a concatenation-based prompting strategy [Touvron et al., 2023b], to facilitate training across the entire length of input.

All prototype models are currently being iterated with our CEDMO project partners (fact-checkers from European organizations), tweaked, and future tests are being designed for them based on empirical results and questionnaires.

3.3 Applications

Several applications demonstrating our contributions are currently deployed and available online due to the CEDMO¹⁶ project, and their testing with future users let us, therefore, present the main applications I and my supervisor Jan Drchal have developed for the tasks:

1. Claim extractor at <https://fcheck.fel.cvut.cz:1830> (figure 3.2) demonstrates the single or multiple claim generation task with our LLaMA-2 or mBART models for English and Czech texts, respectively – I put it together as a GRADIO interactive application and an API
2. <https://fcheck.fel.cvut.cz:1831> runs a FactSearch platform by Jan Drchal, demonstrating our best performing models for the whole fact-checking tasks, integrating the XLM-RoBERTas trained on CsFEVER-NLI data
3. <https://fcheck.fel.cvut.cz:1832> runs the same scheme with our best-performing English models and data

Factual Claim Extraction

This is a prototype CEDMO application to extract factual claims from an arbitrary text.

Text to extract

He said this became possible after Kyiv liberated the "strategically important" village of Robotyne in the Zaporizhzhia region. Russia's military says its forces are still holding on to the village. Ukraine seeks to cut the land corridor to Crimea, which Russia seized in 2014. By doing so, Kyiv would split in two the land Russia occupies in southern Ukraine, making Moscow's supply lines more complicated. Speaking at a recent meeting of French ambassadors in Paris, Mr Kuleba said: "Having entrenched on its [Robotyne's] flanks, we are opening the way to Tokmak and, eventually, Melitopol and the administrative border with Crimea."

Chapter 4

Dissertation plan

This chapter describes my current research agenda and its meaning for my future dissertation thesis on automated fact-checking using NLP methods, which is outlined in the last section.

4.1 Automated claim generation

The article I am currently readying for submission proposes the task of *automated claim generation* as the process of extracting factual claims from a textual document. It has multiple uses in practice, such as assisting the fact-checkers and emulating data for NLP tasks like automated fact-checking and NLI.

Extracting a set of factual, atomic claims from a chunk of naturally formed text poses many challenges – what single piece of information characterizes the text best? How does one resolve the pronouns and coreferences in source text? How does one adapt the extraction scheme for different speakers and stylistic forms?

I find these problems to overlap with those of the *abstractive summarization* task, which has recently seen an advent of efficient solutions based on Transformer models [Zhang et al., 2020, Liu et al., 2022b].

The summarization scheme only requires minor tweaks – preventing it from outputting more than one sentence of output per input and training it on data appropriately chosen to promote the summarization of more than one fact when sampling different claims from the same model using the top- k ¹ and top- p ² [Holtzman et al., 2020] strategies.

An initial training data is derived from XL-Sum [Hasan et al., 2021], ENFEVER and CTKFACTS, and models are trained using mBART, Pegasus, T5 [Raffel et al., 2019], and LLaMA-2 (QLoRA) architectures. Additional experiments are being carried out using the GPT Chat API.

Moving forward, the primary tasks will be a cyclic iteration of claim generation data and models, refining each part after progression in the other, and most importantly, a set of reliable metrics that are explainable and correlate with human judgment. As shown in section 2.5.1, the standard automated summarization metrics are not appropriate as a benchmark for the task.

4.2 Claim generation metrics

The common problem with generative tasks in NLP is that of explaining model reasoning in a human-understandable manner and troubleshooting the prediction faults, such as the

¹Each output token is sampled from the k most probable words in the dictionary

²Each token is sampled from the most probable words which have at most p total probability mass

Figure 4.1: LM-Critic – deciding text fluency viewed as finding local optima of Language Model output probability, reprinted from [Yasunaga et al., 2021]

model hallucination.

For the task of claim generation, where we also face the challenge of the *relevance* of the information extracted by the model, we suggest the use of the following metrics:

1. **Fluency** – *is the claim grammatically correct and intelligible?*

Currently, we are working with two emulations of claim fluency, challenge that is similar to a standard NLP task of Gramatical Error Detection (GED): LM-Critic (Figure 4.1) [Yasunaga et al., 2021] perturbs the claim words and characters to find local optima in output probability of its tokens, using a language model such as GPT-2 as its reference. GPTScore [Fu et al., 2023] uses prompting a LLM (such as GPT-3) to obtain a model-inferred score using few- or zero-shot learning.

Both can be adapted for Czech and the latter is demonstrated in Figure 4.2.

2. **Decontextualization** – *can the claim be correctly interpreted without any additional context from the source document or elsewhere?*

A common problem with machine-extracted factual claims is reusing excerpts from source documents along with inexplicable contextual pronouns (“President won’t sue them”) and relative referencing (“Last year, CTU had 23K students”).

[Choi et al., 2021] proposes decontextualization as a sequence-to-sequence task with two texts on input (s, c) – sentence and context. T5 model [Raffel et al., 2019] is then trained on machine-generated gold data from Wikipedia to output sentence s' such that the truth-conditional meaning of s' in an empty context is the same as that of s in c .

[Mohri et al., 2023] improves upon this, altering the problem formulation to minimization of surrogate loss, rejecting with a fixed predictor, and claiming to get as close as $\sim 3\%$ away from the theoretical limit for the task.

The approaches are reproducible using the Czech Wikipedia corpus and appropriate for further examination.

3. **Atomicity** – *does the claim describe a single entity, relation or process?*

Claim atomicity can be checked using the Relationship Extraction methods such as LUKE [Yamada et al., 2020]. Simply put, the RE task is to identify the entities of a text (persons, institutions,...) and the relations between them (such as (“study at”, Herbert, CTU)). The atomicity evaluation can be converted to a RE task

Central European Digital Media Observatory

Claim extraction and its metrics using GPT

This is a prototype CEDMO application to fact-check a real-world text.

Text to extract

A global search has been launched to find one of the world's most iconic instruments - Paul McCartney's original Höfner bass guitar. McCartney bought the instrument for £30 (\$38) in Hamburg, Germany, in 1961, but it disappeared eight years later. The hunt began after McCartney urged manufacturers Höfner to track down his beloved instrument. The bass features in The Beatles' music of those years, including the hits Love Me Do and She Loves You. Nick Wass is heading Höfner's search project and has joined forces with two journalists in trying to solve the "greatest mystery in the history of rock and roll."

Number of claims to extract

3

Type of text

news article

Model

gpt-3.5-turbo

Clear Submit

Claims

1. Paul McCartney's original Höfner bass guitar, which he bought for £30 in 1961, has been missing since 1969.
2. McCartney has urged Höfner, the manufacturer of the instrument, to launch a global search to find his beloved bass guitar.
3. Nick Wass, along with two journalists, is leading Höfner's search project to solve the "greatest mystery in the history of rock and roll."

Multi-metrics

- **focus = 5** All three claims accurately represent the relevant information presented in the news article, which is about the global search effort launched to find Paul McCartney's missing Höfner bass guitar and the involvement of Nick Wass and two journalists in this project.
- **coverage = 3.5**, since the claims cover the main information regarding the missing bass guitar and the search project, but do not mention the role of the two journalists nor the significance of the instrument to The Beatles' music.

Claim metrics

1. **Paul McCartney's original Höfner bass guitar, which he bought for £30 in 1961, has been missing since 1969.**
 - **fluency = 5** The claim is grammatically correct and well-formed, presenting a factual statement about the missing original Höfner bass guitar that Paul McCartney bought in 1961 for £30.
 - **decontextualization = 4.5** The claim provides the key information about the missing Höfner bass guitar, including its ownership, purchase date, and disappearance, but lacks details about the ongoing global search and the efforts involved.
 - **atomicity = 5** This claim is highly atomic as it presents a single specific fact about Paul McCartney's missing bass guitar, including the purchase date, price, and the year it went missing.
 - **faithfulness = 4.5** The claim is mostly faithful to the news article. The article states that Paul McCartney's original Höfner bass guitar has been missing since 1969, and the hunt to find it began after McCartney urged Höfner to track it down. However, the claim does not mention the involvement of Nick Wass and two journalists in the search project, which slightly deviates from the article.

Figure 4.2: A self-evaluating claim generation model based on GPT-3.5-turbo and GPT-4 [OpenAI, 2023] using the OpenAI API and a single-shot (one gold example given) approach

by attempting to extract such fact triples and mark the claim as atomic if there is at most one such triple found (after removing symmetries)

4. **Faithfulness** – *does the claim only contain information that is consistent with the source document?*

This metric is crucial to pinpoint *model hallucinations* – parts of the claim where the model outputs stray from the information present in the source text and begin to just “make stuff up”. We proceed to use two alternative metrics – a score proposed within the FFCI evaluation framework [Koto et al., 2020] as:

$$\text{AvgTop-}n_{s_j \in X, t_i \in Y'}(\text{BERTSCORE}(t_i, s_j))$$

Where the AvgTop- n simply averages across the top n (say, 5) highest scores, X, Y' are the sets of sentences in the source document and model output, respectively (so, in the claim generation scenario $|Y'| = 1$) and BERTSCORE [Zhang* et al., 2020] is a recently popular similarity score between two sentences that doesn’t compare the texts on a verbatim level (like, e.g., ROUGE [Lin, 2004] which correlates poorly with human judgment) but expresses the sentence similarity as a sum of cosine similarities between their tokens’ embeddings – this should capture semantical relations rather than the word-for-word similarity, which could be beneficial in highly inflected languages such as Czech.

Similar metric called ALIGNSCORE was proposed in [Zha et al., 2023], looking for optimum alignment of output and input parts, in terms of a RoBERTa model [Liu

et al., 2019] trained to detect inconsistencies on 4.7M training examples adapted from various tasks (inference, question answering, paraphrasing,...) and while it is relatively small (355M parameters), it outperforms metrics based on GPT-4 that is orders of magnitude larger.

Empirically, the models work encouragingly well on spotting hallucinations and inconsistencies in English, and while the transduction of BERTSCORE is trivial, using a Czech embedding model such as CZERT [Sido et al., 2021] or FERNET [Lehečka and Švec, 2021], reproducing the success of ALIGNSCORE will require more research and data.

5. **Focus@ k** – *if we generate k claims using this model, what will be the proportion of gold (relevant) information among all the information listed in the generated claims?*

The metric is analogous to the concept of *precision* in the common machine learning applications; however, its deciding gets more ambiguous in the natural language setting, where we are dealing with synonyms and an endless number of possible wordings for every piece of information.

An elegant and functional perspective on the problem has been brought around in QAGS³ evaluation protocol [Wang et al., 2020], where the idea is to use a Question Generation model (QG) to formulate questions in natural language based on all k predicted claims. The questions are then twice answered using a Question Answering (QA) model, giving it knowledge from (i.) the predicted claims (ii.) the gold claims written by a human. The focus is then defined as the proportion of questions with the same answers extracted from the gold and predicted claims among all questions the model can generate from the predicted claims.

6. **Coverage@ k** – *if we generate k claims using this model, what proportion of gold (relevant) information from the source text will be covered?*

Analogous to *recall@ k* in general machine learning, QAGS proposes to generate questions using gold claims and try to answer them using the predicted claims, much like in the *focus* scenario, but vice versa.

4.3 Data Collection

4.3.1 Human-in-the-loop grading of claim generators

To validate the metrics referred to in section 4.2, one needs human-annotated data for the task. I aim to use an experiment similar to that of [Wright et al., 2022], presenting annotators with ordinal scales for the claim qualities and appropriate grading for each metric conditioned by objective rules.

My research will attempt to design the experiment in a way that yields the best data, checking its validity using inter-annotator agreement and other forms of feedback and publishing the data and scheme alongside the other solutions.

4.3.2 Polish dataset scraping

While Czech has its SumeCzech [Straka et al., 2018] and in Slovak, we can still reproduce the SMESum [Šuppa and Adamec, 2020] research, a large-scale single-sentence summa-

³Pronounced “kags”, stands for “Question Answering and Generation for Summarization”

rization dataset in Polish has yet to be established. The closest data I have found is the online news corpus [Szwoch et al., 2022] collected for the purposes of studying political polarization (and nowhere published, despite my e-mail urgences).

A scraping experiment in the Polish media, such as TVP, Rzeczpospolita, Gazeta Wyborcza, Fakt, etc., is therefore being prepared to obtain an appropriate single-sentence dataset for publication – it is also going to be another incremental step toward the dissertation on the overall topic of NLP fact-checking and its stages, focusing on English and West Slavic languages.

4.3.3 Crowd-sourced fact-checking platform

In 2023, other members of our team [Bútora, 2023] with funding from Avast developed a crowd-sourced fact-checking platform⁴, where users gather reputations like on Wikipedia, by sharing check-worthy pieces of information found across the internet, and by their checking with sources.

While I am not directly involved in the implementation of the project apart from early consulting, experiments with FSV CUNI are to be launched, populating this platform with data and users. After the experiments, other data and applications will be delivered, and their processing will be another part of my dissertation project.

4.3.4 CTKFACTS expansion

In 2021/2022, another round of the CTKFACTS annotation experiment (see section 3.1.3) was carried out with the FSV CUNI students, yielding about 5K new data points, including, for example, claims extracted from the Czech Twitter.

The data is being cleaned and examined and will be attached to one of the other upcoming publications and presented in the dissertation thesis.

4.4 Pipeline modernization

As mentioned throughout the chapter 2, the state of the art in NLP has shifted dramatically over the last year, and another of the tasks I am currently working on is the modernization of our pipeline – Claim Generation, Information Retrieval, Natural Language Inference models – and appropriate use of LLMs in the tasks.

So far, I have successfully finetuned LLaMA-2 [Touvron et al., 2023b] for the claim generation task, and we have a LoRA finetuning experimental setup ready for the NLI models. The use of LLaMA-2 and its successors for our tasks will be a topic on its own, as most publicly available LLMs filter out the other languages and focus solely on English.

4.5 The grand scope

Overall, in brief points, the main topics of my dissertation are expected to be:

1. Introduction of the fact-checking task and its data, strong model baselines, and specific properties in the **West Slavic** context
2. An integration of the step of **Claim generation** step into it, based on methods of abstractive summarization

⁴<https://factcheck.fel.cvut.cz>

3. A delivery of reliable **metrics** for the tasks and their validation with expert-level humans
4. Modernization of the fact-checking paradigms and solutions in English and Czech into the age of **Large Language Models**.
5. As the current instruction-tuned Large Language Models exhibit an **ability to explain their reasoning** [Saeed and Omlin, 2023], the methods of eXplainable AI (XAI) may also be integrated into our automated fact-checking framework, giving the fact-checker further insights what is behind the model classification
6. Multiple **validation experiments** are planned with real-world fact-checkers⁵ to testify to the usability of our solutions in the real world

⁵Partners from CEDMO and other projects

Chapter 5

Conclusion

In this study, I have presented my current challenges and their motivation – a desire for an automated scheme to assist fact-checking. The solutions are being proposed in other literature and rely mostly on transformers, which is the current state of the art for nearly every NLP task. The transformer usage paradigm is shifting (from the approach of *fine-tuning* a *pre-trained* transformer to *prompting* or *few-shotting* a Large Language Model), which will impact my dissertation and also yield new challenges in modernizing our previous work.

So far, numerous datasets, most notably the CsFEVER and CTKFACTS, have been collected, a working fact-checking pipeline was deployed on them, and the models we trained were published for further use.

Other tasks are to be established among the scientific public, importantly the claim generation and its model-based metrics, ongoing research such as the claim generation model training, collection of additional data in Czech, English, Polish, and Slovak is to be concluded, and new solutions for the whole problem of automated fact-checking are to be proposed, utilizing the new SOTA methods, such as the Large Language Models.

The point of the precedent chapters of the study was to give insights on what has been done so far, what is its value, what is the context in which this is happening, and what are the likely next steps in the future of my research.

Appendix A

Acronyms

BERT Bidirectional Encoder Representations from Transformers

GPT Generative Pre-trained Transformer

FEVER Fact Extraction and Verification – series of Shared tasks focused on fact-checking

IR Information Retrieval

SOTA State of the Art

XSum Extreme Summarization – summarizing article into one sentence

NLI Natural Language Inference

ČTK Czech Press Agency
